Foundations of modern finance cheatsheet by Oleg L., Page 1 of 2

#### 1 Foundations of Modern Finance I

# Present value of annuities and perpetu-

Perpetuity:  $\frac{CF}{r}$ .

Growing perpetuity:  $\frac{CF}{r-g}$ .

Annuity:  $\frac{CF}{r} \cdot \left(1 - \frac{1}{(1+r)^n}\right)$ 

Annuity with growth:

$$\frac{CF}{r-g} \cdot \left(1 - \frac{(1+g)^n}{(1+r)^n}\right)$$

where r rate of return, g growth rate, ncompounding periods

#### Arrow-Debrew securities. State-space model

 $\phi_1 \dots \phi_n$  state prices  $p_1 \dots p_n$  state probabilities, where  $\sum_{i=1}^{n} p_i = 1$   $X_1 \dots X_n$  state payouts  $P = \sum \phi_i \cdot X_i = \frac{\dot{E}(P)}{(1+\overline{r})},$ 

 $\overline{r} = \frac{E(P) - P}{P} = \frac{\sum p_i \cdot X_i}{P} - 1,$  $E(P) = \sum_{i} p_i \cdot X_i = P \cdot (1 + \overline{r}),$ 

where  $\overline{P}$  is price, E(P) is expected payout,  $\overline{r}$  is expected return.

#### Discounted cash flow and rate of return

r is rate of return,  $r_f$  is risk-free rate of return,  $r - r_f$  is excess return

$$r = \frac{D_1 + P_1 - P_0}{P_0} = \frac{D_1 + P_1}{P_0} - 1,$$

$$P_0 = \frac{D_1 + P_1}{1 + r}$$
With g as growth rate,
$$P = \frac{D}{r - g}, g = \frac{D_1}{D_0} - 1$$

$$P = \frac{D}{r - g}, g = \frac{D_1}{D_0}$$

 $\overline{r} = E(r)$ , expected return,  $\pi = \overline{r} - r_f$  is risk premium

## Relation between real and nominal cash

$$r_{real} = \frac{1 + r_{nominal}}{1 + inflation} - 1$$
For nominal flow,

 $CF \cdot (1 + r_{real}) \cdot (1 + inflation)$ For real flow,

 $CF \cdot (1 + r_{real})$ 

#### Accounting

 $I_t = EPS_t \times b$ , where b - plowback rate  $EPS_{t+1} = EPS_t + I_t \times ROI_t$ 

$$\begin{array}{l} BVPS_{t+1} = BVPS_t + I_{t+1} \\ D_t = EPS_t \times (1-b_t) \end{array}$$

Growth rate  $g = \frac{EPS_{t+1}}{EPS_t} - 1$ With growth  $P_0 = \frac{D}{r-g}$ 

Without growth  $P_0^{nogrowth} = \frac{D}{\pi}$ , where g = 0 and b = 0Growth opportunity  $PVGO = P_0$  - $P_0^{nogrowth}$ 

Horizon value estimation:

PV(Freecashflow) + P/E ratio or P/B ratio or DCF

#### Risk

Expected utility

 $E[u(x)] = \sum p_i \cdot u(P_i),$ where  $p_i$  is probability,  $P_i$  is payout Expected payoff  $E(P) = \sum p_i \cdot P_i$ Relative risk aversion

$$RRA(W) = -\frac{W \cdot u''(W)}{u'(W)}$$

Certainty equivalent  $CE = u^{-1}(E(u(x)))$  $\pi$  - sure loss, risk premium, W is investment amount, so

 $E(u(W \cdot (1+x))) = u(W \cdot (1-\pi))$ 

$$CE = W \cdot (1 - \pi), \pi = 1 - \frac{CE}{W}$$

$$\begin{cases} +x\%, p_1 \\ -x\%, p_2 \end{cases}$$

### $E(u(W \cdot (1+x))) = \sum p_i \cdot u(W \cdot (1+x))$

#### Interest rate conversion EAR/APR

T - compounding interval, fraction yearly: T = 1

monthly:  $T = \frac{1}{12}$ 

daily:  $T = \frac{1}{365}$ P - principal n - number of payment periods, so period payment M is

 $M = P \cdot \frac{APR \cdot (1 + APR \cdot T)^n}{(1 + APR \cdot T)^n - 1}$ 

 $\lim_{T\to 0} 1 + EAR = e^{APR}, \text{ so } APR = \ln(1 + EAR)$ 

 $APR = \frac{(1 + EAR)^{T'} - 1}{T}$ 

 $1 + EAR = (1 + T \cdot APR)^{\frac{1}{T}}$ 

#### **Duration**

duration is  $MD = \frac{t}{1+v}$ 

Macaulay duration is  $D = \frac{1}{B} \cdot \sum_{t} \frac{CF_t}{(1+v)^t} \cdot t$ 

Modified duration is  $MD = \frac{L}{1+v}$ 

Modified duration for perpetuity is  $MD = \frac{1}{2}$ , so Macaulay duration is  $D = \frac{1}{2}$ 

 $MD \cdot (1+y) = \frac{1+y}{y}$ 

#### **Duration based approximations**

 $\Delta v$  is the change in the interest rate, P is the asset price.

 $\Delta P = -P \times MD \times \Delta y$ Convexity *CX* is

 $CX = \frac{1}{2} \cdot \frac{1}{P} \cdot \frac{1}{(1+v)^2} \cdot \sum_{t} PV(CF_t) \cdot t \cdot (t+1),$ 

convexity based approximation is  $\Delta P = P \times (-MD \cdot \Delta y + CX \cdot \Delta y^2)$ 

#### Statistic

Excel functions:

Sample mean AVG()Standard deviation *STDEV.S(*)

 $cov = \frac{1}{T-1} \cdot \sum (r_A - \overline{r}_A) \cdot (r_B - \overline{r}_B)$  $T-1 = \frac{cov}{SD(A) \cdot SD(B)}$ Corellation:  $corr = \frac{cov}{SD(A) \cdot SD(B)}$ 

Portfolio variance:

 $cov_{ij} = SD_i \cdot SD_j \cdot corr_{ij}$  $Var[P_{AB}] = \sum_{i=1}^{N} w_i^2 \cdot SD_i^2 + \sum_{i\neq j} 2w_i w_j \cdot$ 

 $SD_iSD_i \cdot corr_{ij}$ ,  $Var[P] = \frac{1}{n} \cdot SD^2 + \left(1 - \frac{1}{n}\right) \cdot corr \cdot SD \cdot SD,$ 

where SD is an average standard deviation

#### **APT**

For well diversified portfolios:

 $\widetilde{r}_P = \overline{r}_P + \sum b_i \cdot f_i$ , where  $\overline{r}_P$  is expected

 $\overline{r}_P - r_f = \lambda \cdot \beta_P$ , where  $r_f$  is risk free rate,  $\lambda$  is risk price and  $\beta_P$  is factor loading for single factor portfolio. Same  $\overline{r}_P - r_f = \sum_i \lambda_i \cdot \beta_i$  for *i* factors portfolio Return variance:

 $Var(r) = \sum_{i} \beta_{i}^{2} \cdot Var(f_{i}) + Var(\epsilon)$ 

 $cov(A, B) = \sum_{i} \beta_{i,A} \beta_{i,B} \cdot Var(f_i)$ 

#### **APT in Excel**

Discount bond price  $B_t = (1 + y)^{-t}$ , dis- $r_i - r_f = \alpha + \beta_1(r_1 - r_f) + \beta_2(r_2 - r_f) + \epsilon_i$ counted bond duration is t, so modified To estimate  $\beta_1$ ,  $\beta_2$  and  $\alpha$  (in this order):

=  $LINEST(\alpha, \beta_2, \beta_1)$  (reverse order)

#### **Capital investment**

CF = OpRev - OpEx - Tax - CapEx OpProfit = OpRev - OpEx $Tax = \tau \cdot OpProfit - \tau \cdot Depreciation$  $CF = (1 - \tau) \cdot OpProfit - CapEx + \tau$ Depreciation

Work capital: WC = Inventory + A/R - A/P, where A/R accounts receivable, A/P accounts

 $\overrightarrow{CF} = (1-\tau) \cdot OpProfit + \tau \cdot Depreciation CapEx - \Delta WC$ 

#### Alternatives to NPV

Payback period

Choose S so PB = S,  $\sum_{i=1}^{S} CF_i \ge -CF_0$ Discounted payback period:

$$DPB = S, \sum_{i=1}^{S} \frac{CF_i}{(1+r)^i} \ge -CF_0$$

Internal rate of return (IRR) must sat-

$$0 = CF_0 + \sum_i \frac{CF_i}{(1 + IRR)^i}$$

Payback Interval:

$$PI = \frac{PV}{-CF_0}$$

#### 2 Foundations of Modern Finance II Forward rates

Forward interest rate between time t-1

$$f_t = \frac{B_{t-1}}{B_t} - 1 = \frac{(1+r_t)^t}{(1+r_{t-1})^{t-1}} - 1$$

Expectation hypotesis (forward rates at time 0 are predictors of future spot rates, which is not true):

$$E_0[\tilde{r}_1(t)] = \frac{(1 + r_{t+1}(0))^{t+1}}{(1 + r_t(0))^t} - 1 = f_{t+1}$$

#### Forward pricing

Current spot price:  $S_0$ 

Spot price at maturity (random):  $\tilde{S}_T$ Forward price (fixed at time 0):  $F_T$ 

Forward payoff is  $\tilde{S}_T - F_T$ 

 $PV_0(\tilde{S}_T) = e^{-yT}S_0$ , where y is dividend yield

 $F_T = e^{(r-y)T} S_0$ , so dividend yield

$$y = r - T \cdot ln\left(\frac{F_T}{S_0}\right)$$

Currency forward price is:  $F_T = X_0 \cdot e^{(r_{USD} - r_{CHF}) \cdot T}$ 

#### **Futures pricing**

Storage cost  $Cost_t = c \cdot S_t$ . Net convenience yield  $\hat{v} = v - c$ , so  $H_T \approx F_T = e^{(r-\hat{y})T} S_0$ 

Backwardation in terms of convenience yield vs interest rate:  $\hat{y} - r = y - c - r > 0$ 

Contango:  $H_T > S_0 e^{rT}$ 

Backwardation:  $H_T < S_0 e^{rT}$ 

#### Interest rate swaps

Fixed leg is paid at fixed rate  $r_S$ . Floating leg at the end of each period *t* is paid as spot risk-free rate  $\tilde{r}_1(t-1)$ Forward rate to future spot rate:  $PV_0[\tilde{r}_1(T) \text{ at } T+1] = PV_0[f_{T+1} \text{ at } T+1]$ Present value of the fixed leg:  $r_S \times$ 

Present value of the floating leg of the swap:  $\sum_{t=1}^{T} PV_0[\tilde{r}_1(t-1) \ at \ t]$ 

Swap rate:  $r_S = \frac{\sum_{t=1}^T B_t \cdot f_t}{\sum_{t=1}^T B_u} = \sum_{t=1}^T w_t \times$ 

 $f_t$ , where weights  $w_t$  are:  $w_t = \frac{B_t}{\sum_{u=1}^T B_u}$ Alternative formula:  $r_s = \frac{1 - B_T}{\sum_{u=1}^T B_U}$ 

#### Options

S underlying asset price (at time 0).  $S_T$  underlying asset price (at time T). B price of discount bond of par \$1 and maturity T ( $B \le 1$ )

K strike (excercise) price.

T maturity (expriration) date. C price of call with strike K and maturity T.

P price of put with strike K and matu-

European call option payoff:  $CF_T =$ 

The net payoff is:  $max[S_T - K, 0] - C(1 +$ 

Excercise value of a call is S - K. Excercise value of a put is K - S. Price bounds are:  $max[S-KB, 0] \le C \le S$ 

Put-Call parity: C + BK = P + S, where B is  $e^{-rT}$  if continious compounding is used.

#### Corporate securities as options

Equity (E): A call option on firm's assets (A) with K equal to its bond's redemption value.

Debt (D): A portfolio of firm's assets (A) and a short position in the call with  $\vec{K}$ equial to bond's face value *F*.

Warrant: Call option on firm's stock, with stock dilution as a result of excer-

Convertible bond: A portfolio of straight bonds and a call on the firm's Foundations of modern finance cheatsheet

by Oleg L., Page 2 of 2

stock with K related to the conversion

Callable bond: A portfolio combining straight bonds and a short position in a call on these bonds.

$$A = D + E => D = A - E$$
  
 $E = max[0, A - F]$   
 $D = A - E = A - max[0, A - F]$ 

#### Binomial pricing: single period

*r* is the interest rate Stock price change:

Riskless bond price change:

Need to solve system of gauations:

$$S_u \cdot a + (1+r) \cdot b = C_u$$
  

$$S_d \cdot a + (1+r) \cdot b = C_d,$$

where a amount of stock shares (option's delta), b dollars invested into riskless bond B,  $C_u$  is payoff in up state,  $C_d$  is payoff in down state, so current market value of the call option is:  $C_0 = S_0 \cdot a + b$ . Alternative notation:  $\delta u S_0 + b(1+r) = C_u$  $\delta dS_0 + b(1+r) = C_d$ 

where unique solutions is:

$$\delta = \frac{C_u - C_d}{(u - d)S_0}, \ b = \frac{1}{1 + r} \cdot \frac{uC_d - dC_u}{(u - d)}, \text{ so}$$

$$C_0 = \delta S_0 + b = \frac{C_u - C_d}{u - d} + \frac{1}{1 + r} \cdot \frac{uC_d - dC_u}{(u - d)}$$

#### Risk-neutral probability

$$q_{u} = \frac{(1+r)-d}{u-d}, \ q_{d} = \frac{u-(1+r)}{u-d}$$

$$C_{0} = \frac{q_{u}C_{u}+q_{d}C_{d}}{1+r} = \frac{E^{Q}[C_{T}]}{1+r},$$

where  $E^{\mathbb{Q}}[\cdot]$  is expectation under riskneutral probability Q = (q, 1 - q).

#### State prices

$$\phi_u = \frac{q}{1+r}$$
,  $\phi_d = \frac{1-q}{1+r}$   
Alternatively, solve the system:

$$\begin{cases} S_0 = S_u \phi_u + S_d \phi_d \\ \frac{1}{1 + r_f} = \phi_u + \phi_d \end{cases}$$

#### Black-Scholes-Merton formula

$$C_0 = C(S_0, K, T, r, \sigma) = S_0 N(x) - s_0,$$

$$Ke^{-rT} N(x - \sigma \sqrt{T}), \text{ where } x \text{ is: } \overline{x} = \overline{r} - r_f \cdot l,$$

$$risk-free ass expected ex
$$x = \frac{ln\left(\frac{S_0}{Ke^{-rT}}\right)}{\sigma \sqrt{T}} + \frac{1}{2}\sigma \sqrt{T}$$

$$w'\overline{x}$$

$$w'\overline{x}$$$$

So option delta ( $\delta$ ) becomes  $N(x) = \frac{\partial C}{\partial S}$ .  $S_0 \cdot N(x)$  is the dollar mount invested into stock into stock.

 $Ke^{-rT}N(x-\sigma\sqrt{T})$  is the dollar amount borrowed.

#### Put-Call parity with BSM formula

#### **Option Greeks**

Delta: 
$$\delta = \frac{\partial C}{\partial S}$$
  
Omega:  $\Omega = \frac{\partial C}{\partial S} \frac{S}{C}$   
Gamma:  $\Gamma = \frac{\partial \delta}{\partial S} = \frac{\partial^2 C}{\partial S^2}$   
Theta:  $\Theta = \frac{\partial C}{\partial T}$   
Vega:  $v = \frac{\partial C}{\partial \sigma}$ 

# Portfolio with mean-variance preferences $\tilde{r}_p = r_F + \sum_{i=1}^N w_i (\tilde{r}_i - r_f)$ Expected portfolio return:

NOTE:  $\sigma \equiv SD$ ,  $\sigma^2 = Variance$ ,  $\bar{r}_p = r_f + \sum_{i=1}^{N} w_i(\bar{r}_i - r_f)$  $\sigma = \sqrt{Variance}$ 

Optimization:  $Minimize_{\{w_1,\dots,w_n\}}\sigma_p^2$  $\sum_{i=1}^{N} \sum_{i=1}^{N} w_i w_i \sigma_{ii},$ 

where  $\sigma_{ij}$  is covariance between assets, Marginal contribution of asset i to  $y_f$  risk-free yield to maturity  $\sigma_p^2$  is portfolio variance.

Sharpe Ratio:  $SR = \frac{\overline{r}_p - r_f}{\sigma_p}$ , the higher  $= 2Cov(\tilde{r}_i, \tilde{r}_p)$  Marginal contribution of pected YTM

the better.

All portfolios on the CML (Capital Market Line), including Tangency Portfolio, have the highest Sharpe Ratio.

#### **Tangency portfolio analytics**

N risky assets, i = 1, 2, ..., N $\overline{r}$  vector of expected returns  $\bar{x}$  vector of excess returns \( \sigma \) covariance matrix  $\overline{l}$  vector of 1 of size  $(N \times 1)$ w vector of portfolio weights of size risk-free asset weight is 1 - w'l

expected excess return on portfolio is  $w' \sum w = \sum_{i=1}^{N} \sum_{j=1}^{N} w_i w_j \sum_{i,j}$  portfolio  $w'\overline{x} = m$  portfolio expected excess

#### **Solving with Langrange multipliers** $L = w' \sum w + 2\lambda (m - w'\overline{x})$

First order condition (FOC): 
$$\frac{\partial L}{\partial w} = 0$$
  
 $2\sum w - 2\lambda \overline{x} = 0 =>$  Solution:  $w_T = \lambda \sum_{i=1}^{n-1} \overline{x}$ 

Tangency portfolio weights on risky assets sum to one:  $w'_T \cdot l = 1$ , so need to

$$\lambda = \frac{1}{\overline{x}' \sum^{-1} \cdot l}$$

$$w_T = \frac{1}{\overline{x}' \sum^{-1} \cdot l} \cdot \sum^{-1} \overline{x}$$

#### Asset contribution to portfolio

Portfolio return with risk-free asset:  $\tilde{r}_p = \left(1 - \sum_{i=1}^N w_i\right) r_f + \sum_{i=1}^N w_i \tilde{r}_i$ 

Risk premium of asset i:  $\frac{\partial \overline{r}_p}{\partial w_i} = \overline{r}_i - r_f$ 

= Variance of portfolio return:  $\sigma_p^2 = \sum_{i=1}^N \sum_{j=1}^N w_i w_j \sigma_{ij}$ 

portfolio variance  $\sigma_n^2$ :

(1):  $\sum_{i=1}^{N} w_i = 1$ (2):  $\sum_{i=1}^{N} w_i \bar{r}_i = \bar{r}_p$ ,  $\frac{\partial \sigma_p^2}{\partial w_i} = 2 \cdot \sum_{j=1}^{N} w_j \sigma_{ij} = 2 \cdot \sum_{j=1}^{$ 

asset *i* to portfolio standard deviation

$$\frac{\partial \sigma_p}{\partial w_i} = \frac{\partial (\sigma_p^2)^{\frac{1}{2}}}{\partial w_i} = \frac{Cov(\tilde{r}_i, \tilde{r}_p)}{\sigma_p} = \frac{\sigma_{ip}}{\sigma_p}$$
Return to risk ratio  $RRR_{ip}$ :

$$RRR_{ip} = \frac{asset \ risk \ premium}{marginal \ asset \ contrib \ to \ SD} = \frac{\overline{r_i - r_f}}{asset \ risk \ premium}$$

For tangency portfolio:

$$RRR_{iT} = \frac{\overline{r}_i - r_f}{(\sigma_{iT}\sigma_T)} = \frac{\overline{r}_T - r_f}{\sigma_T} = SR_T$$

#### **CAPM derivation**

$$\begin{split} MCAP_{M} &= \sum_{i=1}^{N} MCAP_{i},\\ w_{i} &= \frac{MCAP_{i}}{MCAP_{M}}\\ \tilde{r}_{i} - r_{f} &= \alpha_{i} + \beta_{iM}(\tilde{r}_{M} - r_{f}) + \tilde{\epsilon}_{i}, \text{ where } \alpha \text{ is always } 0, E[\tilde{\epsilon}_{i}] = 0 \text{ and } Cov[\tilde{r}_{M}, \tilde{\epsilon}_{i}] = 0.\\ \sigma(\tilde{\epsilon}_{i}) &= SD \text{ measures non-systematic risk.} \\ SR_{T} &= \sqrt{SR_{M}^{2} + SR_{P}^{2}} \end{split}$$

$$A = E + D, \text{ so } \beta_A = \frac{E}{E + D} \beta_E + \frac{D}{E + D} \beta_D$$

$$r_A = \frac{D}{E + D} r_D + \frac{E}{E + D} r_E$$

$$WACC = w_D r_D + w_E r_E$$
If CAPM holds and debt is riskless, so 
$$\beta_D = 0,$$

$$\beta_A = w_D \beta_D + (1 - w_D) \beta_E = (1 - w_D) \beta_E$$
or 
$$\beta_E = \frac{1}{1 - w_D} \beta_A = \left(1 + \frac{D}{E}\right) \beta_A.$$
Equity cost for levered firm is:

$$r_E = r_A + \frac{D}{E}(r_A - r_D)$$

Unlevered firm  $r_E$  compensates for business risk. Levered firm  $r_E$  in addition compensates for finansial risk from leverage.

#### Default and risk premium

B zero-coupon bond face value P zero-coupon bond current price E[P] expected payoff

Promised YTM: 
$$y = \left(\frac{B}{P}\right)^{1/T} - 1$$
  
Expected YTM:  $\overline{y} = \left(\frac{E[P]}{P}\right)^{1/T} - 1$ 

Default premium = Promised YTM - Ex-

Risk premium = Expected YTM -  $y_f$ With  $\lambda$  as loss rate, p as probability of default and  $\overline{y}$  as yield for bonds of similar risk, promised yield y to sell at face

$$y = \frac{1 - p\lambda}{1 - p\lambda}$$

#### Firm value with debt and taxes

$$V_U = \frac{(1-\tau)X}{1+r_A}$$

$$V_L = \frac{(1-\tau)X}{1+r_A} + \frac{\tau r_D D}{1+r_D} = V_U + \frac{\tau r_D D}{1+r_D}$$
 $X$  pre tax cash flow  $\tau$  corporate tax

 $\pi$  equity tax (dividend and capital gain)  $\delta$  debt tax rate Equity holders CF:  $(1-\pi)(1-\tau)(X-r_DD)$ Debt holders CF:  $(1 - \delta)r_DD$ Total after tax CF:

 $(1-\pi)(1-\tau)X + [(1-\delta)-(1-\pi)(1-\tau)]r_DD$ All equity firm discount rate:  $(1 - \pi)r_A$ 

For debt discout rate is:  $(1 - \delta)r_D$
